(Dated: May 26, 2016)

The nature of the pairing states of superconducting LaNiC$_2$ and LaNiGa$_2$ has to date remained a puzzling question. Broken time reversal symmetry has been observed in both compounds and a group theoretical analysis implies a non-unitary triplet pairing state. However, all the allowed non-unitary triplet states have nodal gap functions but most thermodynamic and NMR measurements indicate fully gapped superconductivity in LaNiC$_2$. Here we probe the gap symmetry of LaNiGa$_2$ by measuring the London penetration depth, specific heat and upper critical field. These measurements demonstrate two-gap nodeless superconductivity in LaNiGa$_2$, suggesting that this is a common feature of both compounds. These results allow us to propose a novel triplet superconducting state, where the pairing occurs between electrons of the same spin, but on different orbitals. In this case the superconducting wavefunction has a triplet spin component but isotropic even parity gap symmetry, yet the overall wavefunction remains antisymmetric under particle exchange. This model leads to a nodeless two-gap superconducting state which breaks time reversal symmetry, and therefore accounts well for the seemingly contradictory experimental results.

The breaking of symmetries in addition to gauge symmetry upon entering the superconducting state usually indicates an unconventional order parameter. Several materials have been found to break time reversal symmetry (TRS) in the superconducting state through the detection of spontaneous magnetic fields below $T_c$ using zero-field muon-spin relaxation ($\mu$SR). In some cases, such as Sr$_2$RuO$_4$ [1] and UPt$_3$ [2, 3], where TRS breaking is also supported by measurements of the polar Kerr effect [4, 5], there exists additional evidence for triplet superconductivity [6–9]. Recently, other superconductors have been reported to show TRS breaking, such as Re$_5$Zr [10] and Lu$_3$Rh$_6$Si$_{18}$ [11], but there is not yet other evidence for unconventional superconductivity and fully gapped behavior is observed. In general the breaking of TRS does not necessarily imply triplet pairing and it is expected for some multiband singlet states such as $s + is$, where there is a phase difference between the gaps which is neither zero or $\pi$ [12]. However a particular conundrum is presented by the TRS breaking in LaNiC$_2$ [13] and LaNiGa$_2$ [14], where it has been argued that as a result of the low symmetry of the orthorhombic crystal structures of both compounds, broken TRS necessarily implies non-unitary triplet superconductivity and all the TRS breaking states have nodes in the gap function [15]. Although evidence for nodal superconductivity was found from some measurements [16, 17], recent specific heat [18, 19], nuclear quadrupole relaxation [20] and penetration depth [19] measurements indicate fully gapped behavior in LaNiC$_2$. In addition, evidence for two-gap superconductivity was found from the specific heat, superfluid density and upper critical field [19]. There have been fewer measurements of superconductivity in LaNiGa$_2$ [21], which has an orthorhombic centrosymmetric crystal structure in contrast to noncentrosymmetric LaNiC$_2$, although fully gapped behavior was inferred from the specific heat [22].

In this Letter, we suggest a solution to this apparent contradiction from measurements of the London penetration depth, specific heat and upper critical field, all of which consistently suggest the presence of two-gap superconductivity in LaNiGa$_2$. Along with previous results of LaNiC$_2$ [19], we establish that nodeless, two-gap superconductivity is a common feature of these compounds. We propose that pairing between electrons with the same spins but on different orbitals gives rise to a triplet superconducting state with even parity pairing in both compounds, where the wave function remains antisymmetric overall due to a sign change upon exchanging electrons between different orbitals. Here additional lowering of the free energy is achieved by an additional field that splits the spin-up and spin-down Fermi surfaces, leading to two distinct gap values.

Polycrystalline LaNiGa$_2$ was prepared by arc melting stoichiometric quantities of La (99.98%), Ni (99.99%) and Ga (99.999%) in argon gas. The ingots were sealed in evacuated quartz tubes and annealed at 600°C for one month. Powder x-ray diffraction measurements showed that the samples are single phase with lattice parameters consistent with previous results [22]. The residual resistivity of $\rho_0 \approx 1.6 \mu\Omega$ cm and $R_{RR} = \rho_{300K}/\rho_A \approx 28$ indicate a high sample quality and a transition temperature $T_c \approx 1.8$ K was determined from the onset of a sharp superconducting transition. The ac magnetic susceptibility was measured in a $^3$He cryostat and heat capacity measurements were performed using a Quantum Design Physical Property Measurement System. The London pene-
The inset shows the components of the two-band model. The solid line shows the fitted two-band model, while the dashed and dashed-dotted lines show models with point and line nodes respectively. The inset shows the components of the two-band model.

$\Delta(T)$ is the gap temperature dependence from Ref. 27 with $\Delta(0) = 1.6 k_B T_c$ and $3.5 k_B T_c$ for the respective models. The presence of multiple electron and hole Fermi surface sheets revealed by band structure calculations [24, 25], as well as a gap significantly smaller than the BCS value derived from fitting $\Delta(T)$ at low temperatures, suggest the possibility of multigap superconductivity. Therefore the data are analyzed using a two-band $\gamma$ model [26], where the gap on each band is calculated self-consistently. The parameters are the partial density of states $n_1$ and $n_2$, the intraband pairing potentials $\lambda_{11}$ and $\lambda_{22}$ along with $\lambda_{12}$ and $\lambda_{21}$ which characterize the interband coupling. The superfluid density of a two-band superconductor can be summarized as $\rho_s(T) = x \rho_1(T) + (1-x) \rho_2(T)$, where $\rho_s(T)$ is the single band superfluid density for the gap $\Delta_i(T)$ ($i = 1, 2$) and $x$ is the relative weight of $\rho_1(T)$ [27]. When using this procedure with $\lambda_{12} = \lambda_{21}$, the free parameters are $n_1, \lambda_{11}, \lambda_{12}, \lambda_{22}$ and $x$. We obtain a good fit across the whole temperature range with the best fitting parameters of $n_1=0.4, \lambda_{11}=0.25, \lambda_{12}=0.153, \lambda_{22}=0.016$ and $x=0.43$. The value of $x$ is close to $n_1$, suggesting the Fermi velocities of each band are similar. The fit to the $\gamma$ model is shown by the solid line in Fig. 2 and the zero temperature gaps are $\Delta_1(0) = 1.29 k_B T_c$ and $\Delta_2(0) = 2.04 k_B T_c$. The smaller gap agrees well with $\Delta(0) = 1.30 k_B T_c$ obtained from fitting $\Delta(T)$ (Fig. 1), as expected for two-band superconductors [28].

Specific heat (C) results for LaNiGa$_2$ are shown in Fig. 3(a), where $C/T$ follows a $T^2$ dependence above $T_c$. The normal state is fitted with $C/T = \gamma_n + \beta T^2$, giving a Sommerfeld coefficient $\gamma_n = 10.54$ mJ/mol K$^2$ and a Debye temperature $\Theta_D = 294$ K from the phonon contribution $\beta T^2$, consistent with previous results[22]. The electronic specific heat ($C_e$) is obtained by subtracting the phonon term, and $C_e(T)/\gamma_n T_c$ is shown in Fig. 3(c). The dashed line shows the specific heat of an isotropic, weakly coupled BCS superconductor, which also deviates from the data. Although $C_e(T)/T$ is not saturated down to 0.35 K, this is consistent with the penetration depth measurements, which only become flat below about 0.25 K.
While \( C_\varepsilon(T)/T \) shows quadratic-like behavior at low temperatures [Fig. 3(b)], a negative value of \( C_\varepsilon(0)/T = -0.93 \text{ mJ/mol K}^2 \) is obtained upon extrapolating to zero temperature, suggesting a nodeless superconducting gap. \( C_\varepsilon(T)/T \) in the superconducting state is fitted using a two band model [29], \( C_\varepsilon(T)/T = xC_\varepsilon^1(T)/T + (1-x)C_\varepsilon^2(T)/T \), where \( C_\varepsilon^1(T)/T \) is the single band \( C_\varepsilon \) with a gap \( \Delta_1(T) \), calculated using the same expression as for the superfluid density fitting. From Fig. 3(c), it can be seen that the data is well described by this model with fitted parameters \( n_1=0.4 \), \( \lambda_{11}=0.261 \), \( \lambda_{22}=0.149 \), \( \lambda_{12}=0.02 \) and \( x=0.31 \). The derived specific heat jump is \( \Delta C/T_c = 1.28 \) and the gap values at zero temperature are \( \Delta_1(0) = 1.08k_BT_c \) and \( \Delta_2(0) = 2.06k_BT_c \). This demonstrates that the specific heat measurements are consistent with two-gap superconductivity, as deduced from the superfluid density fitting.

To determine the upper critical field \( H_{c2}(T) \) of LaNiGa\(_2\), we measured the ac susceptibility \( \chi \) (inset of Fig. 4) and specific heat (inset of Fig. 3(c)) in various magnetic fields. A transition cannot be clearly resolved in the specific heat data for applied fields greater than 0.03 T, the reason for which is not clear and requires further studies. As shown in Fig. 4, \( H_{c2}(T) \) is almost linear near \( T_c \). However, the curvature of \( H_{c2}(T) \) shows a clear upturn at low temperatures, deviating from the Werthamer-Helfand-Hohenberg (WHH) model (dashed line) [30]. Such a negative curvature of \( H_{c2}(T) \) is a common feature of multiband superconductivity. For a multiband system taking into account both interband and intraband couplings, \( H_{c2}(T) \) can be calculated following Ref. 31. The upper critical field was fitted with the same parameters used to fit the superfluid density, so that the only free parameters were the diffusivities of the bands \( (D_1 \text{ and } D_2) \). The data are well fitted by the model (solid line in Fig. 4) and therefore \( H_{c2}(T) \) agrees well with with two-band superconductivity. The obtained value of \( D_2/D_1 \) is 0.15, while the extrapolated zero-temperature upper critical field is \( H_{c2}(0) \approx 0.11 \text{ T} \).

Therefore measurements of the penetration depth, specific heat and upper critical field consistently support nodeless two-gap superconductivity in LaNiGa\(_2\). Two-gap behaviour was also observed in LaNiC\(_2\)[19], suggesting that nodeless, two-gap superconductivity is another common feature of these compounds, in addition to TRS breaking. In what follows we propose a unified view of these materials in which the two phenomena have a common origin.

Significant differences exist between the two materials. Electronic structure calculations reveal that either one or two bands cross the Fermi level \( (E_F) \) in LaNiC\(_2\) [32, 33], while LaNiGa\(_2\) has a very different Fermi surface, with several bands at \( E_F \) [24, 25]. Moreover, whereas the crystal structure of LaNiGa\(_2\) has a center of inversion, that of LaNiC\(_2\) lacks it. As a result, in LaNiGa\(_2\) the spin-orbit coupling may lead to a superconducting state which is a mixture of spin-singlet and spin-triplet [34–36]. In contrast, for LaNiGa\(_2\) such a state is forbidden by symmetry.

Several works have discussed LaNiC\(_2\) and LaNiGa\(_2\) in terms of a conventional BCS pairing mechanism [24, 25, 33, 39] and this scenario leads to fully-gapped superconductivity with two-gap behavior arising from the involvement of two distinct bands. However, such theories are not readily reconciled with the observation of TRS breaking in both compounds [13, 14]. To address this, it was proposed that in LaNiC\(_2\) the broken TRS may arise from a small admixture of triplet pairing to an otherwise largely conventional superconducting order parameter [33]. Alternatively, it was hypothesized that a non-trivial phase factor between the s wave gaps in two different bands (an \( s + is \) state) might be responsible.
for broken TRS [24]. However, the point groups of the crystal structures of LaNiC$_2$ and LaNiGa$_2$ are $C_{2v}$ and $D_{2h}$, respectively, both of which only have one-dimensional irreducible representations [13, 14] whereas a multi-dimensional order parameter is required to break TRS at $T_c$ [37]. In the triplet admixture scenario, the relevant point group is the double group $C_{2v,J}$ whose irreducible representations have the same dimensionality as those of $C_{2v}$. In the $s+is$ scenario, the point group is either $C_{2v}$ or $D_{2h}$, if the bands are strongly-coupled, or the products $C_{2v} \otimes C_{2v}$, or $D_{2h} \otimes D_{2h}$, if they are decoupled, which also only have one-dimensional irreducible representations. Thus in either scenario the broken TRS would require a first-order transition or multiple superconducting phase transitions [15, 40]. While the latter has been observed in UPt$_3$ [38], there is no experimental evidence in these compounds.

In the case of weak spin-orbit coupling the relevant point groups for LaNiC$_2$ and LaNiGa$_2$ are $C_{2v} \otimes S O(3)$ and $D_{2h} \otimes S O(3)$, respectively, both of which have three-dimensional irreducible representations and there are four TRS-breaking superconducting instabilities [13–15], all of them in the purely-triplet channel and thus in stark contrast to the above scenarios. All four instabilities correspond to nonunitary (equal-spin) pairing, for which we expect an additional, subdominant order parameter, in the form of a bulk magnetisation appearing below $T_c$, which may have been observed in LaNiC$_2$ [41]. However, all of these nonunitary triplet states have nodal gap functions, which is clearly inconsistent with this work and Ref. 19.

As a result, we suggest that a new mechanism may be present in these materials. An isotropic gap which does not change sign can result from an on-site interaction, which is not possible for equal spin pairing in a single-orbital model, but could result from a local attraction between electrons with equal spins on different orbitals. The pairing potential has the form $\Delta_{n,m}(k)$, where $n, m$ are orbital indices and $\alpha, \beta$ are the spin indices of the two paired electrons. For an isotropic gap with the formation of Cooper pairs within one orbital, $\Delta_{n,m}(k) = \Delta_{n,\beta}$ and therefore to keep the gap function antisymmetric under the exchange of two fermions, it is necessary that $\Delta_{n,m} = -\Delta_{m,n}$, that is there is singlet pairing between electrons of opposite spins. However if the pairing occurs between electrons on different orbitals, the condition for triplet pairing $\Delta_{n,m}^{\alpha,\beta} = \Delta_{n,m}^{\beta,\alpha}$ can be met if $\Delta_{n,m}^{\beta,\alpha} = -\Delta_{m,n}^{\alpha,\beta}$, that is the change of signs is achieved through an antisymmetric orbital index. Similar scenarios have been proposed to make superconducting instabilities [13–15], all of them in the irreducible representations and there are four TRS-breaking scenarios. All four instabilities correspond to nonunitary $\Delta$ gap with the formation of Cooper pairs within one orbital, $\Delta_{\alpha,\beta}$.

Similar to the conventional two-band behaviour captured by the $\gamma$–model used to fit our data. However, note that the two values of the gap are associated with two different values of the spin, rather than two band indices.

Further hints of an unconventional pairing mechanism come from recent measurements of LaNiC$_2$ under pressure, which reveal a broad superconducting dome, where the maximum of $T_c$ coincides with a crossover from a metallic normal state to one with strongly correlated electronic interactions [45]. One possibility is that fluctuations of the correlated state mediate the pairing interaction, which might then look different from the simple, on-site form used above. Alternatively, the local attraction between equal spins could result from Hund’s rules. Furthermore, our theory provides a mechanism for an on-site attraction leading to triplet pairing, suggesting the possibility of TRS breaking superconductivity mediated by phonons.

To summarize, we performed measurements of London penetration depth, specific heat and upper critical field which show two-gap, nodeless superconductivity in LaNiGa$_2$. The presence of two gaps in both LaNiGa$_2$ and LaNiC$_2$ allows us to propose a novel non-unitary triplet state, where the gap symmetry has even parity. This can reconcile the observation of fully gapped behavior and the breaking of TRS in both compounds and further work is required to elucidate the mechanism which leads to this novel pairing state.
