Starting materials sourced from commercial suppliers were used as received unless otherwise stated. All reagents requiring purification were purified using standard laboratory techniques according to methods published by Perrin, Armarego, and Perrin (Pergamon Press, 1966). Catalytic reactions were run under an atmosphere of dry nitrogen or argon; glassware, syringes and needles were either flame dried immediately prior to use or placed in an oven (200 °C) for at least 2 h and allowed to cool either in a desiccator or under an atmosphere of nitrogen or argon; liquid reagents, solutions or solvents were added via syringe through rubber septa; solid reagents were added inside a glovebox. All optimization reactions were filtered through a sinter funnel charged with a pad of celite and silica for copper removal. Coupling partners for Stille reactions were distilled before use. Anhydrous solvents were obtained by distillation using standard procedures or by passage through drying columns supplied by Anhydrous Engineering Ltd. Anhydrous dichloromethane (CH$_2$Cl$_2$) was purged with argon for 10 minutes prior use. Flash column chromatography (FCC) was performed using silica gel (Aldrich 40-63 µm, 230-400 mesh). Thin layer chromatography (TLC) was performed using aluminium backed 60 F254 silica plates. Visualization was achieved by UV fluorescence or a basic KMnO$_4$ solution and heat. Proton nuclear magnetic resonance spectra (NMR) were recorded using either a Varian 400 MHz, Varian 500 MHz or Bruker AVANCE DRX400 MHz. $^{13}$C NMR spectra were recorded at 100 MHz or 125 MHz as stated. Chemical shifts ($\delta$) are given in parts per million (ppm). Peaks are described as singlets (s), doublets (d), double doublets (dd), triplets (t), double triplets (dt), and multiplets (m). $^1$H and $^{13}$C NMR spectra were referenced to the appropriate residual solvent peak. Coupling constants ($J$) are quoted to the nearest 0.5 Hz. All assignments of NMR spectra were based on 2D NMR data (DEPT-135, COSY, HSQC and HMBC). In situ yields were determined by employing 1,4-dinitrobenzene as an internal standard. Mass spectra were recorded using a Brüker Daltonics FT-ICRMS Apex 4e 7.0T FT-MS (ESI$^+$ mode) and Shimadzu GCMS QP2010+ (EI$^+$ mode). Infrared spectra were recorded on a Perkin Elmer Spectrum One FTIR spectrometer as thin films or solids compressed on a diamond plate. Melting points were determined using Stuart SMP30 melting point apparatus and are uncorrected.

**Intermolecular competition experiment between 1a and d₄-1a**

A competition experiment involving the iodination of equimolar quantities of 1a and deuterio-1a was conducted. At 30% conversion, a 1.6:1 ratio of 2a to d₃-2a was obtained as determined by ¹H/²H NMR analysis against a 1:1 mixture of 1a and d₄-1a. This result confirms that C-H cleavage is kinetically significant, but does not elucidate whether or not this is the rate determining step.
