22 **Abstract**

23 *Physcomitrella patens* is an attractive model system for comparative analyses of leaf development because
24 it evolved leaves (phyllids) independently to flowering plants, yet its genome contains homologues of many
25 gene families that regulate angiosperm leaf development. In addition, *P. patens* phyllids are primarily a
26 single cell layer thick, making it simple to identify the cellular basis of defects that perturb shape.
27 Identification of gene functions in shape determination depends on like for like comparison of mutant
28 versus wild-type plants. Here we show that, if heteroblasty is not perturbed, such comparisons should use
29 phyllid L13 or above in the heteroblastic series, and fully expanded phyllids above P7 in the developmental
30 series. Using a quantitative approach, we show that heteroblastic size variation reflects differences in cell
31 proliferation rather than cell size and shape. A comparison of control to *pinA pinB* mutant phyllid
32 development verifies that PIN proteins promote cell proliferation and suppress expansion to determine
33 phyllid shape. The results and approach that we have generated will be applicable to any study of *P. patens*
34 phyllid development to reveal the cellular basis of phyllid size and shape variations.

35 **Key words**

37 **Main text**

38 **Introduction**

39 The plant evo-devo field aims to identify genes underpinning the radiation of diverse forms during
40 evolution (Harrison, 2017). Leaves and leaf-like organs have evolved multiple times and fulfil
41 photosynthetic functions during plant evolution (Tomescu, 2008; Harrison and Morris, 2018). Whilst the
42 leaves of vascular plants develop in the diploid sporophyte stage of the life cycle, the phyllids of mosses
43 and liverworts develop in the haploid gametophyte stage of the life cycle, and these groups evolved leaves
44 independently (Harrison and Morris, 2018). Moss phyllids each develop from a single cell cleft in a spiral
45 pattern from the gametophore apical cell (Parihar, 1967; Harrison *et al.*, 2009). The phyllid apical cell then
46 cleaves in a herringbone pattern thus establishing the proximo-distal and medio-lateral axes of phyllid
47 development, and later divisions extend both axes independently of the activity of the phyllid apical cell

48 (Harrison *et al.*, 2009). The resultant phyllid is oblanceolate, and except at the point of midrib insertion is a
49 single cell layer thick (Parihar, 1967; Harrison *et al.*, 2009). This property makes moss phyllids an attractive
50 model system for understanding how the activity of genes translates via cell growth and division into
51 overall organ form, particularly since it is possible to image all the cells within a phyllid as it grows (Harrison
52 *et al.*, 2009).

53 Reverse genetic approaches in *Aphanoregma patens* have started to identify genes that regulate phyllid
54 development in mosses to address questions about the genetic mechanisms underlying convergent leaf
55 evolution. Whilst some genetic mechanisms for leaf development are not shared between mosses and
56 flowering plants (e.g. (Sakakibara *et al.*, 2008)), many are. These include *TONNEAU* genes (Traas *et al.*,
57 1995) which regulate microtubule activity and phyllid expansion (Spinner *et al.*, 2010), *PIN* genes (Galweiler
58 *et al.*, 1998, Scarpella *et al.*, 2006) which regulate phyllid width (Bennett *et al.*, 2014; Viaene *et al.*, 2014)
59 and *HD-zipIII* genes (Talbert *et al.*, 1995; McConnell and Barton, 1998; Prigge *et al.*, 2005) which regulate
60 the proximodistal axis of phyllid development and phyllid margin integrity (Yip *et al.*, 2016). These genetic
61 data suggest that many similar mechanisms have been independently recruited to regulate leaf
62 development in mosses and flowering plants. Further *Aphanoregma* mutants such as *ftsZ* (Anja *et al.*, 2009)
63 and *RecQ* (Wiedemann *et al.*, 2018) have phyllids that are smaller than in wild-type plants or have split tips
64 respectively. Analyses of mutant phyllid phenotypes are to date qualitative and at the whole organ scale, so
65 do not reveal the cellular basis of mutant phenotypes. This makes it hard to draw comparisons between
66 wild-type and mutant plants or between studies (e.g. Spinner *et al.*, 2010, Bennett *et al.*, 2014, Viaene *et al.*,
67 2014, Yip *et al.*, 2016). Furthermore, *Aphanoregma* phyllids develop in a heteroblastic series (Barker
68 and Ashton, 2013) and different studies have intercepted this series at different points in development. For
69 these reasons, we have undertaken a quantitative analysis of phyllid development in *Aphanoregma* and
70 developed a simple approach to enable rigorous quantitative comparisons of phyllid phenotypes in wild-
71 type and mutant plants.

72 **Materials and Methods**

73 ***Plant growth and sample preparation***

74 The *Aphanoregma patens* Gransden strain was used in all experiments except for control versus mutant
75 phenotype comparisons, which used *pinA pinB* mutant strain and a *GH3::GUS* strain used to engineer the
76 *pinA pinB* mutants (Bierfreund *et al.*, 2003; Bennett *et al.*, 2014). All plants were grown as spot cultures on
77 BCDAT plates as described elsewhere (Whitewoods *et al.*, 2018). Phyllids were removed and laid out on
78 plates containing 0.8 % agar in heteroblastic series counting from the gametophore base. Phyllids L3, L10,
79 L14, L16, L18, and L20 were selected from each heteroblastic series and soaked in 1% chloral hydrate.
80 Cleared phyllids were rinsed with de-ionised water three times and transferred to 2 M NaOH for 2 h. They
81 were then rinsed and stained in toluidine blue prior to mounting under a coverslip with the abaxial side of
82 the phyllid lying flat against the slide (see supplementary protocol).

83 ***Microscopy, image capture and image segmentation***

84 Phyllids were imaged using a Leica DMRXA microscope with a 20 x objective. Length measurements were
85 made from the tip to the base along the midrib, and width measurements were made perpendicular to the
86 midrib at the widest point of each phyllid. Images were further processed with ImageJ (Schindelin, *et al.*,
87 2012) to generate a map of all cell outlines within the phyllid, and the length, width, area and aspect
88 (length to width) ratio of all cells was measured using ImageJ (see supplementary protocol). Using QGIS
89 software (QGIS Development Team, 2017), these metrics were plotted back against cell maps of each
90 phyllid to visualise cell shape trends within and between phyllids as heat maps.

91 **Results**

92 ***Heteroblastic variation in phyllid length reflects cell division, not expansion***

93 To quantify patterns of phyllid development, the five largest gametophores were teased out from five
94 different 6 week-old plants (n = 25 in total). Phyllids were removed from each gametophore, arranged in a
95 heteroblastic series and measured as described in the Materials and Methods section. Length
96 measurements were found to progressively increase to a maximum at phyllid L13 (Figure 1A), and thus
97 subsequent fully expanded phyllids in the heteroblastic series had a similar length (Figure 1A, Table S1).
98 However, phyllid length decreased towards the gametophore apex from P7 to P1 due to incomplete

99 expansion (Figure 1B, Table S2). To investigate the effect of cell size and shape on phyllid size, we mapped
100 the outline of cells in fully expanded phyllids throughout the heteroblastic series (Figure 1C). Quantitative
101 analyses of cell number per phyllid, cell length, cell width, cell area and cell aspect ratio supported previous
102 analyses showing that the increase in phyllid length in a heteroblastic series reflects an increase in cell
103 number rather than cell length increases (Figure 1D-H, Table S3).

104 ***Cell shapes are heterogeneously distributed***

105 To identify the cellular basis of differences in phyllid size and shape, we first plotted the distribution of
106 quantitative cell shape measures against phyllid cell maps using QGIS software (Figure 2A-D). This analysis
107 revealed a proximo-distal gradient in cell length, with high cell lengths in cells at the base and margin
108 (Figure 2A). There was a decrease in cell width from the base of the phyllid to the tip, but marginal cells
109 were the narrowest (Figure 2B). Cell area decreased from the base to the tip of phyllids (Figure 2C). In
110 contrast, cell aspect ratio increased from the midrib to the edge of the phyllid, with a slight decrease
111 towards the tip (Figure 2D). Thus, cells in different regions of *P. patens* phyllids had different quantitative
112 attributes.

113 ***Multivariate analysis distinguishes three phyllid regions with distinct cell shapes***

114 To determine whether the quantitative measures above were sufficient to distinguish phyllid regions with
115 different cellular identities, we performed a multivariate analysis using K means cluster analysis (Figure 3).
116 This identified three highly supported cell shape classes in all samples (Figure 3A and 3B, Table S4). The
117 spatial distribution of shape classes was plotted against phyllid cell maps using QGIS software. Whereas
118 cells at the base of the phyllid were long and broad, cells at the edge were long and narrow, and cells at the
119 top were shorter and narrower than cells at the base (Figure 3B, 3C). There was no difference in the cell
120 shape distribution or the proportions of each cell type between phyllids within a heteroblastic series. Thus
121 heteroblasty reflects differences in cell number, not cell shape and size.

122 ***Comparison of control with mutant phyllid phenotypes***

123 *Aphanoregma pinA pinB* mutants have defective auxin transport and previously identified phyllid defects
124 (Bennett *et al.*, 2014; Viaene *et al.*, 2014). To determine whether a quantitative approach would be useful
125 in mutant phenotype characterisation, we compared *pinA pinB* mutant development to development in a
126 *GH3::GUS* line used to engineer the *pinA pinB* mutant (Bierfreund *et al.*, 2003; Bennett *et al.*, 2014). To
127 identify any heteroblasty defects in mutants, we first measured phyllid lengths (Figure 4A, Table S5). Whilst
128 *pinA pinB* phyllids were longer than *GH3::GUS* phyllids, both lines reached a maximum length by phyllid L13
129 in the heteroblastic series (Figure 4A, 4B). Further analyses between genotypes compared the number of
130 cells and mean cell length, width, area and aspect ratio in fully expanded phyllids. This revealed that *pinA*
131 *pinB* mutants have fewer cells per phyllid than *GH3::GUS* plants, and that cells are longer and larger with a
132 similar width in mutant versus *GH3::GUS* plants (Figure 4C, Table S6).

133 To investigate the effect of genotype on cell shape, size and number in different phyllid regions we applied
134 the multivariate analysis and clustering approach described above to data from mutant and control
135 phyllids. This showed fewer cells in the top phyllid region in *pinA pinB* mutants compared to *GH3::GUS*
136 plants and slightly more cells in the edge region (Figure 4D, 4E). The base region had comparable cell
137 numbers. While there was no significant overall difference in cell area, cells in *pinA pinB* mutant phyllids
138 were slightly but significantly longer than cells in *GH3::GUS* lines (Figure 4D, Table S7). Comparison of
139 phyllid regions showed that cells from the edge and top regions in *pinA pinB* mutants were slightly larger
140 than equivalent cells in *GH3::GUS* plants (Figure 4D), and *pinA pinB* mutants had significantly wider cells in
141 the edge region and narrower cells in the top region with correspondingly altered aspect ratios. Cells in the
142 base region were unchanged in both width and aspect ratio in *pinA pinB* mutants compared to *GH3::GUS*
143 plants. The differences above were clear from heat maps plotting quantitative data and the output from
144 cluster analyses (Figure 4E). These data suggest that phyllid size and shape differences in *pinA pinB* mutants
145 are due to a small global increase in cell size and a reduction in the number of cells in the top phyllid region
146 (Figure 4E).

147 Discussion

148 The data above show that simple quantitative measures can be used to highlight the cellular basis of

149 differences in phyllid shape and size between control and mutant *P. patens* plants. A previous analysis of
150 phyllid development documented an increase in length through the heteroblastic series and increasing cell
151 number per phyllid correlating with progression through the heteroblastic series up to L10 (Barker and
152 Ashton, 2013). By further sampling we found that phyllid length and cell number per half phyllid reach a
153 maximum by phyllid L13 in the heteroblastic series. Our analyses also show that, regardless of size or
154 position in the heteroblastic series, phyllids contain three quantitatively distinct populations of cells.
155 Differences in phyllid size and shape reflect cell proliferation rather than cell expansion and cell shape
156 change. Thus, future studies wishing to draw like for like comparisons of phyllid development should rule
157 out heteroblastic defects and select phyllids L13 or above from the heteroblastic series and P8 or above
158 from the developmental series, and the quantitative approach that we have developed may be helpful in
159 characterising the cellular basis of mutant phenotypes.

160 Previous analyses have shown that the plant hormones cytokinin and auxin regulate phyllid size. Whilst
161 cytokinin promotes medio-lateral and proximo-distal proliferation, auxin suppresses medio-lateral and
162 proximo-distal proliferation and promotes anisotropic growth (Barker and Ashton, 2013). *pinA pinB*
163 mutants show similar phyllid phenotypes to normal plants treated with exogenous auxins (Bennett *et al.*,
164 2014; Viaene *et al.*, 2014), suggesting that PIN function is normally required to drain auxin from the phyllid
165 and confer phyllid shape by regulating the interplay between cell proliferation and growth. Here we have
166 refined this analysis to show that *pinA pinB* mutant phyllids have fewer cells in the top region, suggesting
167 that the role of PIN and auxin for cell proliferation may be localised, whereas its role in regulating cell
168 expansion is broader. The combination of simple hormonal inputs with the ability to understand
169 development at the gene, cell and organ scales makes the *P. patens* phyllid an attractive model system for
170 future analyses of mechanisms underlying organ shape determination in plants.

362

363 Table S6

Plant	Number of cells per half phyllid	Mean cell area (μm^2) $\pm$ standard deviation	Mean cell length (μm) $\pm$ standard deviation	Mean cell width (μm) $\pm$ standard deviation	Mean cell aspect ratio $\pm$ standard deviation
<i>GH3::GUS a</i>	310	1795 $\pm$ 1238	104 $\pm$ 43	22.8 $\pm$ 7.5	4.9 $\pm$ 2.6
<i>GH3::GUS b</i>	296	1677 $\pm$ 976	99 $\pm$ 35	22.6 $\pm$ 5.9	4.6 $\pm$ 2.0
<i>GH3::GUS c</i>	310	1360 $\pm$ 796	95 $\pm$ 38	19.6 $\pm$ 5.4	5.3 $\pm$ 3.1
<i>GH3::GUS d</i>	278	1728 $\pm$ 1199	101 $\pm$ 39	21.6 $\pm$ 7.2	4.9 $\pm$ 2.1
<i>GH3::GUS e</i>	287	1528 $\pm$ 986	96 $\pm$ 41	21.4 $\pm$ 6.3	4.8 $\pm$ 2.7
<i>pinA pinB a</i>	193	1922 $\pm$ 1050	127 $\pm$ 50	21.4 $\pm$ 7.5	6.3 $\pm$ 2.7
<i>pinA pinB b</i>	164	2287 $\pm$ 1522	127 $\pm$ 45	23.9 $\pm$ 8.6	5.6 $\pm$ 2.2
<i>pinA pinB c</i>	196	1972 $\pm$ 1488	117 $\pm$ 44	22.5 $\pm$ 7.9	5.4 $\pm$ 2.0
<i>pinA pinB d</i>	155	1968 $\pm$ 989	127 $\pm$ 44	21.8 $\pm$ 6.0	6.2 $\pm$ 2.5
<i>pinA pinB e</i>	235	1586 $\pm$ 930	117 $\pm$ 46	19.0 $\pm$ 5.3	6.3 $\pm$ 2.6

364

365 Table S7

Table S7: Quantitative comparison of <i>GH3::GUS</i> to <i>pinA pinB</i> mutants						
Region and background		Mean number of cells ± standard deviation (n phyllids = 5)	Mean cell area (μm^2) ± standard deviation	Mean cell length (μm) ± standard deviation	Mean cell width (μm) ± standard deviation	Cell Aspect Ratio ± standard deviation
Top	<i>GH3::GUS</i>	227 ± 12	1247 ± 82	82 ± 2.6	20 ± 0.9	4.1 ± 0.1
	<i>pinA pinB</i>	116 ± 32	1362 ± 81	95 ± 2.0	20 ± 0.9	5.0 ± 0.2
Edge	<i>GH3::GUS</i>	36 ± 7	1787 ± 138	161 ± 9.4	17 ± 0.8	10 ± 0.9
	<i>pinA pinB</i>	44 ± 11	2028 ± 104	169 ± 5.3	19 ± 0.7	9.3 ± 0.5
Base	<i>GH3::GUS</i>	33 ± 12	3941 ± 213	151 ± 3.7	35 ± 1.4	4.5 ± 0.1
	<i>pinA pinB</i>	29 ± 10	4034 ± 403	164 ± 14	34 ± 1.8	4.9 ± 0.5

Moss phyllid cell segmentation protocol

1. Toluidine blue staining phyllids:

- i. Remove phyllid from desired position in heteroblastic series.
- ii. Clear in Hoyer's medium overnight (Anderson, 1954).
- iii. Wash tissue with deionised water at least three times.
- iv. Place tissue in 2M NaOH for 2 hours.
- v. Wash tissue with deionised water at least three times.
- vi. Stain with 0.05% Toluidine Blue for two minutes.
- vii. Destain for 10 minutes in water.
- viii. Wash two or more times with DI water and leave until ready to mount.

Region of toluidine blue stained phyllid.

2. Image capture

- i. Capture images with a maximum pixel resolution of 1024 in the longest dimension using a 20 x objective.
- ii. Save images of the same phyllid with sequential tags e.g. Myname_Treatment_shoot01_Leaf20_img0001.tif
- iii. Ensure there is >25% overlap between fields of view in each image.

3. Image stitching (see supporting illustrations below)

- i. Open Fiji.
- ii. Open an image selected to represent a series.
- iii. Select from "Plugins" >> "Segmentation" >> "Trainable Segmentation".
- iv. Use tools on the FIJI task bar to **pan around your image** and **zoom in and out** in the "Trainable Segmentation" window.
- v. Use the **freehand drawing tool** to draw along some of the cell walls, on the image in the "Trainable Segmentation" window.
- vi. When a set of cell walls is highlighted (marked by a yellow line), click "Add to class 2" (the line will turn green) and repeat this step a few times.
- vii. Then mark a non-cell wall area i.e. within a cell or outside of the phyllid, and click "Add to class1".
- viii. Click the Train classifier tool.
- ix. If you are happy with the result (I am in this instance), then click the button "Save data".
- x. Save the data in a new file named "trainingdata".
- xi. Click the button "Create result" to generate a black and white (binary) image of the result.
- xii. Save the image "classification result" (with a more appropriate name) e.g., TS_Original_name_of_image.tif
- xiii. Complete this segmentation step for all images, saving each one separately.
- xiv. Move all images from a single phyllid to a single folder.
- xv. Stitch the images together using Plugins >> Stitching >> Deprecate >> Stitch directory with images (unknown arrangement).
- xvi. Click "Browse" from the pop up box and select a folder where the images for one phyllid are saved.
- xvii. Click OK
- xviii. If there are stitching problems, try stitching fewer images at once and later putting part stitched images together.
- xix. Save the image.

4. Manual refinement of stitched images using GIMP (see supporting illustrations below)

- i. Open GIMP.
- ii. Open the stitched image from step 3.
- iii. Save the image with a GIMP (.xcf) extension.
- iv. Select the whole image, and copy and paste.
- v. Click "new layer" twice, and create a transparent layer.
- vi. Select the new layer using the layers panel.
- vii. Select the paint bucket icon from the tools panel, and fill the new layer in black by clicking anywhere on the picture.
- viii. Move the new layer below the pasted layer.
- ix. Select the pasted layer from the layers panel.
- x. Then select "Colors" >> "Threshold" and click "OK" to turn the image to black and white.
- xi. Select the pencil button from the tools layer and adjust the size and brush to a similar width to wall widths.
- xii. Trace a black line just to side of the midrib. Maintain a continuous line of white the length of the midrib to the left of the midrib. By holding the shift key as you click you will see a line which will be traced by the pencil tool and become black.
- xiii. Once you have drawn a black line through the centre on the phyllid entirely separating the two sides, change the colour of the pencil tool to white and look for cell walls that are not complete and join them (if unsure compare with original microscope image). Only do this for one side of the phyllid.
- xiv. If cell walls appear fused, change the pencil tool to black and fill cells to ensure they have continuous black centre.
- xv. Select the "fuzzy select tool".
- xvi. Click on the white of the image to select a contiguous area comprising the cell wall outlines of a half phyllid (if both sides are selected the black line through the midrib was incomplete).
- xvii. Hold "Ctrl" and press "I" to invert the previous selection.
- xviii. "Delete" the speckles that are not connected to cell walls to leave a segmented half-phyllid.
- xix. "Flatten" the image and save it as a .tif file.
- xx. Open the .tif file "Gimp_edited_stitched_phyllid_01.tif" in Fiji.
- xxi. Select "Process">> "Smooth" and smooth three times.
- xxii. Convert the image to binary mode (select "Process" >> "Binary" >> "Make Binary").
- xxiii. Select "Plugins" >> "Skeleton" >> "Skeletonize(2D/3D)".
- xxiv. Select "Process">> "Smooth" and smooth three times.
- xxv. Convert the image to binary mode again and save it as a new .tif file ("Skeleton_edited_phyllid_01.tif").
- xxvi. Touch up traces by referring to original microscope image using the pencil tool and bucket fill tools in GIMP or in Fiji.
- xxvii. Skeletonize, smooth, and make binary the image as above and and save it as a new .tif file "Finished_phyllid_01.tif"

5. Cell size/shape analysis (see supporting illustrations below)

- i. Open the "Finished_phyllid" file in Fiji.
- ii. To set the scale, select "Analyze" >> "Set Scale".
- iii. To scale later images in a series to the first image, "Click to remove scale" and tick the box "Global".

- iv. Calculate the scale by opening an image with a measured scale bar in it. Select the "Straight" free hand line tool and draw a line across the length of the scale bar.
- v. Select the "Analyze" >> "Set Scale" tool and type the length of the scale bar into the "Known distance" box. Fiji automatically calculates the conversion ratio of pixels to units for you.
- vi. Select the measurements you want to make using select "Analyze" >> "Set measurements".
- vii. Select areas of the image to be measured using "image" >> "adjust" >> "threshold", and slide the threshold scale so that the whole image turns red.
- viii. Select "Analyze" >> "Analyze Particles".
- ix. Tick the boxes "Exclude on edges", "Display results" and "Add to manager".
- x. Save the results from the "Results" window by selecting "File" >> "Save As" e.g. "Cell_data_Phyllid01.csv".
- xi. Use data for variable comparison in other packages

6. Phyllid size analyzes (see supporting illustrations below)

- i. Open the "Finished_phyllid" file in Fiji.
- ii. Set the scale as described in Section 5.
- iii. Select areas of the image to be measured using "image" >> "adjust" >> "threshold", and slide the threshold scale so that only the cell walls are outlined in red.
- iv. Set the "Analyze particles" option to "include holes option".
- v. Select the "Straight" line drawing tool and then select "Segmented line".
- vi. Extend the line by clicking along the length of the phyllid outline and when finished right click.
- vii. Select the "Analyze" >> "Measure" option to return the length of the line you just drew.
- viii. Save this new results window, "File" >> "Save As" (ie. Whole_Leaf_measurements_Leaf01.csv).
- ix. Use data for variable comparison in other packages
