Dear Editor

Re: Spatz ES, Krumholz HM, Moulton BW. The new era of informed consent. Getting to a reasonable-patient standard through shared decision making.

Spatz et al highlight important changes in UK law arising from Montgomery in 2015. The Supreme Court’s formal rejection of physician-centred, paternalistic information disclosure in informed consent was welcome and long overdue. While it is true the ruling set out the rationale for a ‘reasonable patient’ standard, our reading of the case suggests that, in fact, the judges were laying out the requirement for doctors to tailor information provision to meet the needs of the individual patient. As a means of achieving this, the Court emphasised that careful dialogue between physician and patient should be the cornerstone of the informed consent process. However, as Spatz et al discuss, barriers that prevent these ideals of patient-centred communication and decision-making being realised in everyday practice are numerous and complex. Physicians need both skill and time to carefully explore the important beliefs and goals that inform a patient’s decision-making about healthcare. Thus, while welcome, it is uncertain how the ruling in Montgomery helps physicians improve the way they approach informed consent.

The ‘reasonable patient’ standard is at once both confusing and helpful in addressing patients’ information needs. On the one hand, it is a somewhat abstract concept that does little to help physicians tailor information to the individual. Without a clear understanding of who a ‘reasonable’ patient might be, the temptation exists to over disclose; that is provide vast amounts of information in the hope that all bases are covered. It is well recognised that this practice can be counterproductive, potentially resulting in heightened levels of confusion and anxiety. On the other hand, the ‘reasonable patient’ standard might serve best if viewed as a baseline from which more meaningful, person-centred conversations develop. The key to this approach is engagement of patients and frontline clinicians in work that aims to define what baseline, or core, information
about a given surgery or other intervention is most valuable to the ‘reasonable’ majority. Guided by expertise in ethics and research, and input from patient groups we are now beginning to explore how best to implement this concept in routine practice. Indeed, in the UK, professional bodies and Royal Colleges laid down guidance for this approach to informed consent and decision-making years before *Montgomery* was heard. We are in agreement with Spatz and co-authors that this case has revitalised the discourse around informed consent. This momentum should be exploited so that, as the authors conclude, the benefits for all stakeholders can be realised.
