ABSTRACT

Uveitis is defined as intraocular inflammation. It is an extra-articular manifestation of many forms of joint disease which include spondyloarthritis, juvenile idiopathic arthritis, and Behcet's disease. Rheumatologists may be asked to consult on patients with uveitis in order to identify an associated systemic illness. Diagnoses such as spondyloarthritis, sarcoidosis, and interstitial nephritis with uveitis are frequently overlooked by referring ophthalmologists. Alternatively rheumatologists may be asked to help manage the immunosuppression including biologics which can be required to treat a subset of patients with uveitis. This review is written to provide rheumatologists with the necessary information to facilitate collaboration in co-managing patients with uveitis.

Imagine a symphony orchestra in which the conductor cannot coordinate the play of the wind instruments with the strings or percussion. Imagine a basketball or soccer team that has not mastered the concept of passing the ball. Imagine an epidemiologic study in which the statisticians and those who conceptualized the study, each have different understandings of the study's purpose. Many endeavors represent a gestalt for which the anticipated goal requires multiple parts; and the whole is greater than the sum of those parts. Since rheumatologists see patients with multi-system disease, they are well aware of this need for collaboration. Uveitis, also known as intraocular inflammation, is a prototypical illness that begs for collaboration. Uveitis is often best assessed and optimally treated by an inter-disciplinary team. In this review, we seek to prepare rheumatologists with information that can facilitate the success of this collaborative effort.

BACKGROUND

The term, uvea, derives from the Latin word for grape. The Roman anatomists felt that peeling away the outer layer of the eye, the cornea and sclera, left a grape-like structure: the iris, ciliary body, and choroid (see Figure 1). Any portion of the uvea can be inflamed and often the inflammation involves adjacent structures (see Figure 2). So anatomic subsets of uveitis include iritis (synonymous with anterior uveitis), iridocyclitis, intermediate uveitis, posterior uveitis (such as choroiditis, retinochoroiditis, chorioretinitis), and panuveitis. Just as increased leukocytes in synovial fluid are indicative of synovitis, so leukocytes in either the aqueous humor or vitreous humor are taken as evidence of uveitis, even though neither the anterior chamber that is filled with aqueous humor nor the vitreous cavity is technically a part of the uveal tract.

Uveitis has a prevalence of roughly one per thousand ¹. Several forms of uveitis are episodic and the prevalence is usually stated as a point prevalence meaning that active disease was present at the time of the survey. Despite its relative rarity, uveitis accounts for approximately the same amount of visual morbidity as either macular degeneration or diabetic retinopathy ², although the latter two diseases are generally more commonly recognized by the public as major causes of visual loss. The duration of some subsets of uveitis probably accounts for this paradox. Both macular degeneration and diabetic retinopathy are diseases that occur toward the end of life. In contrast, uveitis might start in childhood or early adulthood and persist through decades.

THE UVEITIS-RHEUMATOLOGY INTERFACE

Patients with uveitis often do need a rheumatologist. As shown in Table I, many systemic, rheumatic diseases can involve both the joints and the uveal tract. Furthermore, most forms of uveitis are immune-mediated and respond to immune suppression, a type of therapy that is outside the expertise of most ophthalmologists.

Just as arthritis has multiple causes, so uveitis has multiple etiologies. Broad etiologic categories are provided in Table 2. The majority of patients with uveitis have an immune-mediated process. This is supported by observation of leukocytes in the eye and by the known ability to produce uveitis in laboratory animals by stimulating the immune response. But just as systemic lupus and rheumatoid arthritis differ in the preferred approach to therapy even though both are immune-mediated, so it is likely that the preferred treatment for a form of uveitis, such as that secondary to juvenile idiopathic arthritis, will differ from the optimal therapy for another form of uveitis such as that secondary to sarcoidosis. Currently, however, most therapy for non-infectious uveitis is determined more by the severity and the anatomic location rather than the etiology, although some notable exceptions are slowly emerging.

Although case reports rarely elucidate pathogenesis, the course of a physician who survived Ebola infection may reveal clues about the intersection between uveitis and rheumatic diseases³. The patient contracted Ebola in Africa and was flown to Atlanta for care. Although he experienced multi-organ failure, he survived. Fourteen weeks after presentation, he had a severe uveitis and the Ebola virus could be recovered from his eye, presumably because the eye is an immune-privileged site. The virus was no longer detectable in blood. At the time that the uveitis developed, he also had low back pain and enthesitis, symptoms suggestive of a spondyloarthropathy, although the uveitis was intermediate and posterior, locations which are not typically inflamed with ankylosing spondylitis.

For joint swelling, we narrow the differential diagnosis based on parameters such as which joints are involved, whether the disease is symmetric or asymmetric, whether the onset was acute or insidious, and the patient's age and gender. Similarly, uveitis subsets are recognized by such variables as the anatomic portion of the uveal tract which is inflamed, by whether the disease is unilateral or bilateral, by whether the inflammation is chronic or episodic, by whether the onset began suddenly or insidiously, and of course, by the patient's age and gender. Both Behcet's disease and ankylosing spondylitis, for example, are associated with uveitis. Both Behcet's disease and

ankylosing spondylitis might be associated with low back pain, peripheral arthritis and diarrhea. Oral sores are often present in HLA B27-associated reactive arthritis, just as they are present in Behcet's disease. But the uveitis associated with ankylosing spondylitis almost always affects only one eye at a time, lasts no longer than 3 months, predominantly affects the anterior uveal tract, may cause hypopyon (pus in the anterior chamber of the eye; see Table 3 for a glossary of relevant terms), and tends to be recurrent⁴. The uveitis associated with Behcet's disease is also recurrent but rarely is the eye completely uninfamed between attacks. The uveitis associated with Behcet's disease is usually bilateral. It is usually both an anterior and intermediate uveitis (intermediate uveitis is recognized by leukocytes in the vitreous humor) or a panuveitis, often with retinal vasculitis. While both diseases cause hypopyon, the eye of a patient with ankylosing spondylitis and hypopyon is red, tender, and sensitive to light; fibrin is frequently present in the anterior chamber. In contrast, hypopyon in association with Behcet's disease need not cause pain or redness. Fibrin is rarely present. In some instances, history alone can help distinguish the two entities since history will usually help determine if one or both eyes are affected or the duration of the eye inflammation. But other subtleties, such as the presence of retinal vasculitis, require a specialist eye examination to detect. Thus, the ophthalmologist potentially can help the rheumatologist make a diagnosis and the rheumatologist can assist the ophthalmologist in differential diagnosis of the systemic disease and collaborate with the management of immunosuppression.

The co-existence of uveitis and arthritis is also not well understood despite how frequently this occurs as is shown in Table 1. Some specific forms of uveitis are discussed in Table 4. Both the eye and joint do share some biochemical similarities such as the presence of hyaluronic acid, type II collagen, and aggrecan. Uveitis and arthritis also occur together in several animal models such as the SKG mouse⁵, adjuvant arthritis in rats⁶, and aggrecan-induced arthritis in BALB/C mice⁷. The co-existence suggests a shared pathogenesis, but in the aggrecan model, mice which do not produce gamma interferon develop far more severe uveitis, while the arthritis is dramatically ameliorated⁷. Similarly characterizing the genetics of the uveitis associated with HLA B27 shows that ankylosing

spondylitis and acute anterior uveitis share a variety of predisposing genes such as HLA B27 itself, the IL-23 receptor, and ERAP-1. At the same time, there are identifiable genes such as IL-6R, probably IL-10, and IL-18R1 that seem to influence solely the susceptibility to acute anterior uveitis⁸.

DIFFERENTIAL DIAGNOSIS AND LABORATORY TESTING

The heterogeneity of uveitis has multiple implications. In terms of differential diagnosis, it is obviously critical to distinguish an infection from an immune-mediated cause of uveitis. Some infections, such as syphilis and tuberculosis, can be quite variable in terms of their presentation within the eye and frequently enter into the differential diagnosis. Some of the more common infectious causes of uveitis include herpes simplex, herpes zoster, toxoplasmosis, and cytomegalovirus (the latter usually in an immunocompromised host). Most infections of the uveal tract cause characteristic changes that can be recognized with a slit lamp examination or with indirect ophthalmoscopy. The “partnership” between a rheumatologist and ophthalmologist, in our opinion, is such that the rheumatologist must trust that the ophthalmologist has excluded an infection; both specialists must be aware that a patient who fails to respond to immunosuppression could have an overlooked infectious cause for her disease. Likewise, two other etiologies, masquerade syndromes and drug-induced disease, are relatively rare, but each has distinct therapeutic implications. The most common uveitis “masquerade” is probably a B cell lymphoma that is usually confined to the brain and the eye^{9,10}. It typically occurs bilaterally in patients who are over 45. This diagnosis can easily be missed. Medications do not usually cause uveitis, but possible culprits include iv bisphosphonates¹¹, TNF inhibitors¹², checkpoint inhibitors¹³ and several antibiotics¹⁴.

In rheumatology, distinguishing gout from rheumatoid arthritis as a cause of joint swelling will markedly change the therapeutic strategy. Most forms of non-infectious uveitis are approached by a treatment algorithm that is not impacted by the cause of the uveitis. Two prominent exceptions are

Behcet's disease and the anterior uveitis associated with juvenile idiopathic arthritis. For Behcet's disease, a monoclonal antibody that inhibits TNF is used frequently because of the dramatic efficacy¹⁵. For the anterior uveitis associated with JIA, the more frequent use of methotrexate and/or a TNF inhibitor such as adalimumab has improved the prognosis for this disease markedly¹⁶.

The above considerations regarding differential diagnosis obviously impact the search for an etiology. The rheumatologist is often tasked with finding a systemic, immune-mediated cause, but should not be the practitioner who diagnoses an infection or masquerading malignancy as a cause. As is true of differential diagnosis in general, the history is key and pattern recognition aids greatly in the goal. Some forms of uveitis such as Behcet's disease or Vogt-Koyanagi-Harada (VKH) syndrome are clinical diagnoses without a definitive laboratory test. Other diagnoses, like Crohn's disease, ulcerative colitis, or sarcoidosis, can be established or supported by biopsy or imaging, but the procedure may be too costly, too toxic (radiation from a CT scan of a young person), too unlikely to yield positive results, or too uncomfortable (colonoscopy) to recommend on a routine basis. Our practice is to choose tests selectively based on clues gained from the examination or history. For example, multiple areas of serous elevation of the retina can be detected on examination and confirmed by testing such as optical coherence tomography or fluorescein angiography. The finding suggests a diagnosis of VKH.

The most common systemic disease associated with uveitis is spondyloarthritis. Roughly half of all patients with sudden onset, non-infectious, anterior uveitis in Europe or North America are HLA B27 positive¹⁷. Recent studies, one from an emergency room in Dublin, Ireland¹⁸ and another from Spain involving 798 subjects and a collaboration between rheumatologists and ophthalmologists¹⁹, concluded that roughly 80% of patients with B27-associated acute anterior uveitis have axial spondyloarthritis based on ASAS criteria. This observation held although both studies excluded any patient with uveitis who had a known spondyloarthropathy. Spondyloarthritis is less common among those who have anterior uveitis and are HLA B27 negative, but the diagnosis remains surprisingly

frequent¹⁹. Older studies using more stringent criteria to diagnose spondyloarthritis had also concluded that spondyloarthropathy was endemic among patients with anterior uveitis^{4,20}.

Rheumatologists who are unaware of this association will frequently fail to recognize the clinical significance of the chronic inflammatory back pain that afflicts many with anterior uveitis.

Another critical cause of uveitis to appreciate is sarcoidosis. In a study from the Cleveland Clinic, 57% of women over 61 years of age with idiopathic uveitis had normal chest x-rays but chest CT evidence for sarcoidosis²¹. We have recently found a similar, slightly lower yield by performing chest CTs on patients with idiopathic uveitis over 40 years of age²². In addition, we noted that 21% of those discovered to have sarcoidosis on chest CT also had cardiac sarcoidosis with associated ventricular tachycardia²². Thus, recognition of the systemic illness had potentially life-saving implications. A study from Japan reached a similar conclusion about uveitis and cardiac sarcoidosis²³.

While most systemic rheumatic diseases associated with uveitis such as Behçet's disease are diagnosed on the basis of the clinical presentation, tubulointerstitial nephritis with uveitis (TINU) is another of those easily overlooked entities. Rheumatologists might be asked to see a patient with TINU because the patient has bilateral red eyes and photophobia from the anterior uveitis and the patient is typically systemically ill with fever, myalgias, a markedly elevated erythrocyte sedimentation rate, mild anemia, and mildly abnormal liver enzymes^{24,25}. Unless one is cognizant of the diagnosis and requests a measurement of beta₂ microglobulin in the urine, the diagnosis is frequently overlooked.

In virtually every series of patients with uveitis, a diagnosis of "idiopathic" disease is the most common etiology noted²⁶. Other terms to describe idiopathic uveitis include non-classifiable, primary uveitis or undifferentiated disease²⁷.

Despite the breadth of the differential diagnosis for uveitis, the rheumatologist should be able to take a relatively targeted approach to laboratory testing²⁸. The examination by the ophthalmologist should have identified any suspicion for a masquerade syndrome or an infectious cause. The detailed

Accepted Article

history should point to most of the possible associated systemic, immune-mediated diseases. If history and exam have failed to point to a probable cause, we screen for syphilis since this infection can be latent for many years and its uveal manifestations are protean. In addition, we obtain a chest x-ray as sarcoidosis might be asymptomatic in the lungs and this is also useful as a screen for tuberculosis. The sensitivity for either ocular tuberculosis or sarcoidosis using chest x-ray is probably 50% or worse. Because of the extensive radiation, we usually do not obtain a chest CT scan to search for sarcoid unless the patient is over 40 years of age²². In the US, we also do not screen for tuberculosis exposure unless the patient has a specific risk factor for tuberculosis such as birth outside the United States or a history of incarceration²⁹. Additional tests might be useful to monitor therapy such as a complete blood count and metabolic panel. Targeted testing is also useful if the presentation suggests a specific entity. For example, we often test for HLA B27 if the patient presents with unilateral, acute, anterior uveitis. We check urine for beta₂ microglobulin for patients who present with a bilateral, sudden onset, anterior uveitis. We consider multiple sclerosis if the patient relates neurological symptoms that might be explained by this diagnosis.

THERAPY

The heterogeneity of uveitis has impacted the ability to design clinical trials. The relative rarity of vision threatening uveitis is such that different etiologies are usually combined into one clinical trial. However, the manifestations of a disease such as birdshot retinochoroidopathy are such that the endpoint for treating it differ greatly from the endpoint in treating an inflammation such as Behcet's disease. This challenge in trial design may have contributed to the failure of promising therapies such as voclosporine (a congener of cyclosporine), secukinumab (anti IL-17A)^{30,31}, gevokizumab (anti IL-1 beta)³² or intravitreal rapamycin³³ to show consistent benefit in clinical uveitis trials.

Most practitioners treat uveitis initially, especially anterior uveitis, with topical corticosteroids. Although these are frequently effective, their penetration posterior to the lens is limited. In addition, use of topical corticosteroids can be complicated by cataractogenesis or elevated intraocular

pressure. One formulation, difluprednate, has greater ability to treat inflammation posterior to the lens, but it also has a greater tendency to cause a cataract or glaucoma. If topical corticosteroids fail, a locally injected corticosteroid such as triamcinolone can be useful. However, in addition to being an uncomfortable injection, risks include cataract, glaucoma, lid ptosis, and rarely retinal detachment. Triamcinolone can be injected directly into the vitreous humor where it has increased benefit and increased risk of intraocular infection or hemorrhage. Oral corticosteroids represent an additional option, but long-term use has toxicity well known to rheumatologists³⁴. Antimetabolites including mycophenolate mofetil, methotrexate, and azathioprine are popular corticosteroid-steroid sparing drugs used by uveitis experts³⁵. Additional options include calcineurin antagonists such as cyclosporine or tacrolimus³⁶, alkylators like cyclophosphamide, or long-lasting corticosteroid implants delivered either by surgery or injection.

The rheumatologist has a major role to play in managing the therapy of a subset of patients with ocular inflammatory disease. Many ophthalmologists are comfortable prescribing oral corticosteroids but rarely resort to steroid sparing medications³⁷. The dosage of prednisone or its equivalent is often such that the treatment has considerable morbidity. An NIH sponsored trial known as MUST (Multicenter Uveitis Steroid Trial) for patients with non-infectious, intermediate, posterior or panuveitis recently showed superior efficacy for systemic immunosuppression as with anti-metabolites compared to a sustained release of fluocinolone into the vitreous humor of the eye. This conclusion was based on visual acuity with 7 years of follow-up³⁸³.

Progress in approval of new therapies for uveitis is hampered by the relative rarity of specific forms of uveitis, by the variety of presumed causes, and by the heterogeneity of outcomes that might define successful therapy. In two time to treatment failure trials reported in 2016, adalimumab showed clear-cut benefit for non-infectious intermediate, posterior or panuveitis^{39,40}. In most instances, adalimumab is indicated for patients who have failed therapy with oral corticosteroids as well as another oral immunosuppressant such as methotrexate or mycophenolate mofetil. The

responsiveness of Behcet's disease to adalimumab or infliximab is such that the authors' sometimes consider such therapy without a trial of an anti-metabolite ⁴¹. Multiple sclerosis (MS) can be associated with intermediate uveitis ⁴². As MS is a relative contraindication to inhibiting TNF, this diagnosis may need to be excluded prior to starting adalimumab therapy for uveitis.

It is rare to prescribe a biologic for anterior uveitis, since most patients with anterior uveitis can be controlled with topical medication alone. An exception is the uveitis characteristically associated with one subset of patients with juvenile idiopathic arthritis (JIA). The typical JIA patient with chronic uveitis has disease that begins between the ages of two and eight and affects a few joints. The majority have a positive ANA and are female. The SYCAMORE study tested the efficacy of adalimumab for patients with JIA whose uveitis was active despite methotrexate and topical corticosteroids ⁴³. The trial was halted early since the evidence for benefit was apparent. Another randomized controlled trial used a different outcome measure, quantification of protein in the anterior chamber of the eye, and also concluded that adalimumab was useful for the chronic anterior uveitis associated with JIA ⁴⁴.

These successes have encouraged additional uveitis trials such as one assessing the benefit of the Jak inhibitor, filgotinib, for indications similar to those supporting the use of adalimumab. Many emerging biologics, however, have not been studied rigorously for possible benefit in the treatment of uveitis. And while uveitis is increasingly targeted in therapeutic trials, a search of the website, clinicaltrials.gov in February, 2018, identified only 7 current or prior randomized controlled trials for uveitis. A similar search for rheumatoid arthritis identified 54 trials. Finally, although some ophthalmologists are comfortable prescribing immunosuppression without close physician collaboration, virtually all ophthalmologists lack an infrastructure that is prepared to deal with the systemic infectious complications which are rare but unavoidable when one suppresses the immune system.

To aid physicians who care for patients with uveitis, several international groups have recently offered guidelines to assist in the care of patients with ocular inflammatory diseases ^{45, 46}. The FOCUS

(Fundamentals of Care for Uveitis) group consisted of 146 international experts who graded the strength of the evidence and who used consensus methodology.⁴⁵

Patients with spondyloarthritis tend to have recurrent episodes of uveitis. As most of these episodes are anterior, last for no more than 3 months, and can be managed with topical corticosteroids alone, the issue of prophylaxis often does not arise. Several medications do reduce the frequency of uveitis. The use of sulfasalazine to prevent attacks of uveitis in patients with spondyloarthritis is supported by randomized controlled trials^{47,48}. Monoclonal antibodies that neutralize TNF, especially adalimumab or infliximab, also prevent attacks of uveitis⁴⁹, but these are not generally prescribed if the sole reason is to prevent attacks of anterior uveitis. At this time, extensive data on how treatments such as secukinumab or tofacitinib affect recurrent uveitis in patients with spondylitis have not been published.

In the future, therapies delivered locally to the eye might become the treatment of choice for ocular inflammation. Locally injected corticosteroid into the eye itself can be very effective, but the therapy is limited, in part because the medication frequently causes cataract and glaucoma. Gene therapy for inherited retinal degeneration has now been FDA approved and is successful in part because the injected gene enters a confined space with minimal worries about expression in other tissues⁵⁰. In contrast to polyarticular rheumatoid arthritis, successful gene therapy for ocular inflammation needs to target no more than two locations. In the decades ahead, one or more locally delivered inhibitors of inflammation might become standard of care for uveitis.

CONCLUSION:

We recognize the challenges to familiarize oneself with a group of diseases which one cannot fully assess by using the tools in a conventional rheumatology clinic. And we empathize with the time requirements that impair optimal management of a patient whose illness requires two or more subspecialists to confer. Mechanisms that facilitate communication with an ophthalmologist include interdisciplinary clinics and case conferences to discuss patients whose illness lies in the interstices between these two disciplines. The gratification of practicing medicine derives primarily from the

Accepted Article

opportunity to improve the welfare of our patients. That welfare is best served if we as rheumatologists share our knowledge and experience, while welcoming the collaboration of ophthalmologists who quite literally have a different view of our patients and their disease. Just as a conductor of a symphony orchestra coordinates multiple musicians, physicians can and should achieve a similar collaboration.

Figure legends:

1. Anatomy of the eye. The uveal tract includes the iris, ciliary body, and choroid. It is shown in lavender.
- 2A. Anterior uveitis is defined as inflammation of the iris and/or ciliary body.
- 2B. Intermediate uveitis is diagnosed when inflammatory cells in the vitreous humor are the predominant finding.
- 2C. Posterior uveitis is diagnosed if the retina and/or choroid are inflamed.
- 2D. Panuveitis is diagnosed if inflammation is present in the anterior uvea, the vitreous humor, and the retina or choroid. It is also possible to have anterior and intermediate uveitis if the retina and choroid are not involved or intermediate and posterior uveitis if inflammation in the anterior chamber is minimal or non-existent.

Diagnosis	Comments
Adverse reaction to medication	Drugs include TNF inhibitors, intravenous bisphosphonates, checkpoint inhibitors
Ankylosing spondylitis	Affects about 40% of patients with AS; usually unilateral, sudden onset, anterior, and recurrent
Behcet's syndrome	Affects about 60 to 80% of patients with Behcet's; usually bilateral, recurrent, often severe with associated retinal vasculitis
Blau syndrome and other auto-inflammatory syndromes	For Blau, uveitis is a common manifestation of an uncommon disease, usually bilateral with chorioretinitis; optic nerve edema or uveitis are also reported in NOMID or other auto-inflammatory syndromes
Crohn's disease	Uveitis and scleritis can be associated, often along with skin and joint disease; phenotype of uveitis resembles PsA-uveitis phenotype
Juvenile idiopathic arthritis	In the pauci-articular, early onset, ANA + subset, usually a bilateral, insidious onset, chronic anterior uveitis. Uveitis also associated with juvenile AS or juvenile onset PsA
Kawasaki's disease and rarely other forms of vasculitis	Bilateral, mild anterior uveitis in association with conjunctivitis. PAN, GPA, LCV, or GCA very rarely cause uveitis.
Lyme disease	Rare but reported cause of uveitis.
Psoriatic arthritis	Affects about 7% of patients with PsA; can be bilateral, chronic, anterior and intermediate, and insidious in onset
Reactive arthritis	Conjunctivitis is classical eye manifestation but sudden onset, unilateral, anterior uveitis is well described
Relapsing polychondritis	Can cause iritis, episcleritis, or scleritis
Rheumatic fever	Very rarely associated with uveitis
Sweet's syndrome	Rarely reported with uveitis
Systemic lupus erythematosus	Rarely causes uveitis or optic neuritis; often causes lacrimal gland disease; can cause cotton wool spots or choroidal vasculopathy
Ulcerative colitis	Uveitis or scleritis less common than with Crohn's disease but clearly associated.
Whipple's disease	Vitreous humor inflammation can be associated

Table 1. The differential diagnosis of uveitis in association with arthritis. Although this table includes rare causes of arthritis and uveitis such as Blau syndrome or Whipple's disease, it does not include everything within the differential diagnosis. For example, tuberculosis could cause a uveitis and an arthritis simultaneously and some patients with arthritis of unknown cause also develop uveitis. Abbreviations: AS=ankylosing spondylitis; NOMID=neonatal onset multi-system inflammatory disease; PsA=psoriatic arthritis; ANA=anti-nuclear antibody; PAN=polyarteritis nodosa; GPA=granulomatosis with polyangiitis; LCV=leukocytoclastic vasculitis; GCA=giant cell arteritis.

Broad categories of disease associated with uveitis	Comments
Infections	Includes viruses such as HSV, VZV, and CMV; syphilis, toxoplasmosis, and tuberculosis among other infections
Masquerade syndromes	Includes B cell lymphoma, leukemia, and retinal detachments
Medication reactions	See Table 1
Ocular syndromes	Includes birdshot retinochoroidopathy, pars planitis, acute multifocal placoid pigmentary epitheliopathy, and multifocal choroiditis with panuveitis
Systemic immune-mediated disease	See Table 1; in addition includes multiple sclerosis, tubulointerstitial nephritis with uveitis, and Vogt-Koyanagi-Harada syndrome
Trauma	Penetrating trauma can cause sympathetic ophthalmia; surgical trauma as in cataract surgery usually causes some self-limited inflammation
“idiopathic”	Also called primary or undifferentiated uveitis; probably the most common diagnosis in a uveitis clinic

Table 2. Abbreviations: HSV=herpes simplex virus; VZV=varicella virus; CMV=cytomegalovirus

Table 3. A Glossary of Terms Often Used by A Uveitis Specialist

Anterior uveitis: inflammation predominantly anterior to the lens of the eye.

Band keratopathy: deposition of calcium in the corneal epithelium. It is a common finding in the uveitis associated with JIA.

Cystoid macular edema: a common complication of uveitis that affects central vision and is often treated by a local injection of corticosteroid.

Flare: the diffraction of the slit lamp beam caused by the increased protein in the anterior chamber that results when the blood aqueous barrier is disrupted as in anterior uveitis.

Intermediate uveitis: inflammation predominantly in the vitreous humor. Neither the vitreous humor nor the anterior chamber technically are a part of the uveal tract, but leukocytes in either usually indicate a uveitis just as cells in the synovial fluid usually indicate a synovitis.

Keratic precipitates: the concretions of cells adherent to the endothelium of the cornea as seen with a slit lamp examination. Large concretions are called “granulomatous” and are seen in such diseases as sarcoidosis, tuberculosis, and herpes zoster infection.

Panuveitis: inflammation simultaneously in the anterior chamber, the vitreous humor and the retina and/or choroid.

Posterior synechiae: the adherence of the iris to the lens. This is a non-specific finding which is nonetheless much more common in some forms of uveitis (such as that associated with HLA B27 or in sarcoidosis) than in others.

Posterior uveitis: inflammation that involves the choroid and often adjacent structures such as the retina.

Retinal vasculitis: an abnormality of retinal vessels such as increased vascular permeability. Retinal vasculitis is a common feature of many forms of uveitis and does not correlate well with the occurrence of a systemic vasculitis.

SUN criteria: an acronym for the Standardization of Uveitis Nomenclature, an international consortium that helped to define terms related to uveitis.

Diagnosis	Comment	Lab Testing
Behcet's disease	Typically a bilateral, recurrent, potentially blinding panuveitis associated with retinal vasculitis	No definitive test; strictly a clinical diagnosis
Birdshot retino-choroidopathy	A chronic, bilateral intermediate and posterior uveitis very strongly associated with HLA A29 and frequently treated by chronic immunosuppression	Almost all patients are HLA A29+
Blau syndrome	A very rare, autosomal dominant form of uveitis associated with mutations in the nucleotide binding domain of <i>NOD2</i> , a gene which codes for an important component of the innate immune system which recognizes bacterial cell wall	Genotyping identifies the mutations known to be associated with this syndrome
HLA B27-related:	Typically, a sudden onset, self-limited (resolves within 3 months), anterior, recurrent, unilateral uveitis. Most uveitis from any cause is anterior and 50% of those with a sudden onset of anterior uveitis are HLA B27 positive, most of whom have some form of spondyloarthropathy. Usually can be managed by topical corticosteroids.	HLA B27 typing; sacroiliac imaging to help diagnose associated spondyloarthritis
Idiopathic	The most common diagnosis in most series from a uveitis clinic. The term is used to mean a form of uveitis that does not fit a diagnostic niche. Other suggested terms include non-classifiable, undifferentiated, or primary (as opposed to secondary to another condition such as ankylosing spondylitis).	A diagnosis made when all other diagnoses have been excluded
Juvenile idiopathic arthritis associated uveitis	Characteristically a bilateral, insidious onset, chronic (lasting longer than 3 months), anterior uveitis, especially likely in patients with JIA who have a pauci-articular, early onset,	A +ANA is supportive but it is neither sensitive nor specific

	ANA positive form of arthritis	
Pars planitis	A relatively common form of uveitis that usually begins insidiously and causes inflammation in the vitreous humor resulting in prominent floaters. (However, the majority of patients with floaters do not have pars planitis.) The disease is named for the pars plana, an anatomic area immediately posterior to the ciliary body and a site where leukocytic concretions are found in this disease.	A clinical diagnosis based on the location of inflammation; occasionally associated with multiple sclerosis so a brain MRI is sometimes obtained.
Primary intraocular lymphoma	A very rare form of uveitis, usually occurring in individuals over 45, and presenting as bilateral cells in the vitreous humor, sometimes with subretinal infiltrates, and often in association with central nervous system lymphoma	Definitive diagnosis is made by characterization of malignant cells in the vitreous humor or on retinal biopsy.
Sarcoidosis	A form of uveitis with “promiscuous” or highly varied presentations ranging from anterior uveitis to retinal vasculitis with or without chorioretinal lesions. Ocular inflammation and pulmonary disease are the two most common initial manifestations of sarcoidosis and it accounts for a relatively common systemic illness among patients in a uveitis clinic.	Chest computed tomography is the most sensitive test. Biopsy is rarely required if symmetric hilar or mediastinal adenopathy is present. ACE, lysozyme, and interleukin-2 receptor have questionable specificity and limited sensitivity.
Syphilis	Late secondary or tertiary syphilis are in the differential diagnosis for any patient labelled as having “idiopathic” uveitis.	FTA or comparable test is preferred. RPR can be negative in up to 40% of patients with uveitis secondary to syphilis.
Tubulo-interstitial nephritis with uveitis	A form of uveitis that is typically sudden onset, bilateral and mostly anterior with a variable amount of vitreous humor inflammation. The disease has an extremely strong association with HLA DRB1*0102. Patients with TINU are typically	Elevation of urine beta ₂ microglobulin is a sensitive way to support the diagnosis. Renal biopsy is definitive but often not required. Serum blood urea nitrogen or serum creatinine have limited sensitivity.

	systemically ill with fever, myalgias and arthralgias as well as a markedly elevated sedimentation rate.	
Tuberculosis	A rare form of uveitis in the United States, but a very common form of uveitis in countries such as India or Saudi Arabia. Also a very difficult diagnosis to confirm as the organism is rarely cultured from the eye. The diagnosis should be considered if the patient has a risk factor for TB (such as being born outside the US or a history of incarceration) or if the illness does not respond to immunosuppression such as oral corticosteroids.	Culture is the ideal confirmatory test, but it is often negative. PCR, when available, is a good alternative. Interferon gamma release assays and skin test responses are useful in confirming exposure to tuberculosis, but neither establishes if active infection is present.
Vogt-Koyanagi-Harada syndrome	An autoimmune form of uveitis with the triggering antigen putatively being tyrosinase. Patients are almost always either Asian, native American, or Spanish speaking. The uveitis is a bilateral, severe panuveitis with serous retinal elevation. Additional symptoms may include headache, meningismus, eighth nerve abnormalities, and vitiligo.	Fluorescein angiography and/or optical coherence tomography should show characteristic serous elevation of the retina.
Whipple's disease	A rare but treatable cause of uveitis in association with arthritis. The presentation in the eye is generally cells in the vitreous humor.	Identification of the causative organism, <i>Tropheryma whippeli</i> , in the vitreous humor or elsewhere

Table 4. Forms of Uveitis of Potential Special Interest to Rheumatologists. Abbreviations: ACE=angiotensin converting enzyme; FTA=fluorescent treponemal antibody; RPR=rapid plasma reagin; PCR=polymerase chain reaction.
