### **METHODS**

MCS is a cohort of 19,517 children born in the UK between 2000-2002. The children were selected through the Child Benefit system with over-sampling from Wales, Scotland and Northern Ireland. Oversampling also occurred from areas with higher concentrations of Black and Asian families, and from deprived areas.

All data were collected at face-to-face interviews. At nine months of age, data were collected on pregnancy, birth and early life including breast feeding (breast milk intake for any period of time), any antenatal maternal smoking and socio-economic status (based on main carer's last known job), delivery by caesarean section (CS), exposure to damp or condensation, exposure to pollution, grime and environmental problems, number of siblings, childcare use (informal e.g. family members and formal e.g. childminder, nursery etc.), maternal history of atopy (none, asthma and eczema, asthma or eczema), maternal pre-pregnancy body mass index (BMI) (underweight, normal, overweight, obese, morbidly obese), maternal age at birth of child. At 3, 5, 7 and 11 years of age, longitudinal data were collected for respiratory symptoms (including wheeze ever and recent wheeze – defined as parental reporting of wheezing or whistling in the chest – in the last 12 months), asthma-diagnosis (based on parental reports) and child's atopic diseases (diagnosis of eczema and hay fever), exposure to smoking (positive if exposure occurred at any time-point in the same room as the child). Ethnicity was coded as Caucasian or non-Caucasian.

### **Statistical Analysis**

We used LatentGOLD 5.1 (Statistical Innovations, Boston, Ma., USA) to define the optimal number of phenotypes to study. Children reporting recent-wheeze for at least three time-points were assigned a 4-digit string with the digits assigned 1 or 0 for recent-wheeze at 3, 5, 7 and 11 years. Thus "0000" signified never wheezed and "1111" signified wheezing at all-time points. Where there were three reports of recent-wheeze, the missing time period was assigned an "asterisk". For the term and preterm-born children who had data available at 3 or 4 time points 4 classes were chosen as the first non-significant p-value and the lowest BIC. The class posterior probability was used to assign each wheezing pattern to the class of wheezing-phenotype which they had the highest probability of belonging to. The machine driven approach was used for all the wheezing patterns.

## **Web Appendix 2**

### **RESULTS**

#### **Web Table 1**

Web Table 1 compares children who were or were not included. A greater percentage of preterm- and term-born children for whom wheezing data were not available were male, from lower socio-economic classes, had lower rates of breast-fed or asthma-diagnosis, less exposure to post-natal smoking, had younger mothers, a greater percentage of maternal BMIs were outside the normal weight range, were more likely to be from an ethnic minority, were more likely to be exposed to pollution, grime and environmental problems, had lower rates of being in formal or informal childcare but were less likely to be atopic. The term-born children not included also had lower birth-weight z-score and higher exposure to antenatal maternal smoking and had more siblings in the household.

## Web Tables

**Web Table 1** – Demographics of the Preterm- and Term-Born Children With and Without Wheezing-Phenotype Data. United Kingdom, Year of Birth 2000-2002

	Term children with wheezing phenotype data	Term children without wheezing phenotype data	Preterm children with wheezing phenotype data	Preterm children without wheezing phenotype data
